Write Short Units of Code   ✕   ⋮

Guideline

> Small units are easier to understand, reuse, and test.

> When writing new units, don't let them grow above 15 lines of code.

Refactoring candidates

☐ `Version.buildVersions()`

☐ `Code128Reader.decodeRow(int,BitArray,Map)`

☐ `HighLevelEncoder.lookAheadTest(CharSequence,int,i...`

> When a unit grows beyond 15 lines of code, you need to shorten it by splitting it in smaller units of no longer than 15 lines of code.

Write Simple Units of Code   ✕   ⋮

Guideline

> Keeping the number of branch points (if, for, while, etc.) low makes units easier to modify and test.

> Try to limit the McCabe complexity, that is number of branch points minus 1, in a unit to at most 5.

> You can reduce complexity by extracting sub-branches to separate units of no

Write Code Once   ✓   ⋮

Guideline

- ❯ When code is copied, bugs need to be fixed in multiple places. This is both inefficient and error-prone.

- ❯ Avoid duplication by never copy/pasting blocks of code.

- ❯ Reduce duplication by extracting shared code, either to a new unit or to a superclass.

Keep Unit Interfaces Small

Guideline

> Keeping the number of parameters low makes units easier to understand and reuse.

> Limit the number of parameters per unit to at most 4.

> The number of parameters can be reduced by grouping related parameters into objects.

Separate Concerns in Modules ✓ ⋮

Guideline

> Keep the codebase loosely coupled, as it makes it easier to minimize the consequences of changes.

> Identify and extract responsibilities of large modules to separate modules and hide implementation details behind interfaces.

> Strive to get modules to have no more than 10 incoming calls.

> The list on the right side contains the top 30 of modules that violate this guideline, sorted by severity. The severity is indicated by the colors of the checkboxes.

Couple Architecture Components Loosely

Guideline

> Having loose coupling between top-level components makes it easier to maintain components in isolation.

> Do this by minimising the amount of interface code; that is, code in modules that are both called from and call modules of other components (throughput), and code in modules that are called from modules of other components (incoming).

> You can hide a component's implementation details through various means, e.g. using the "abstract factory" design pattern.

> The list on the right side contains the top 30 of modules that violate this guideline, starting with the modules that contain throughput code.

Keep Architecture Components Balanced ✕   ⋮

Guideline

> Balancing the number and relative size of components makes it easier to locate code.

> Organize source code in a way that the number of components is between 2 and 12, and ensure the components are of approximately equal size (keep component size uniformity less than 0.71).

> Organising components based on functionality makes it easier to divide your code into components.

Keep Your Codebase Small ✓   ⋮

Guideline

Volume overview

> Keeping your codebase small improves maintainability, as it's less work to make structural changes in a smaller codebase.

> Avoid codebase growth by actively reducing system size.

> Refactor existing code to achieve the same functionality using less volume, and prefer libraries and frameworks over "homegrown" implementations of standard functionality.

> Strive to keep volume below 20 Man-years.

# Automate Tests   ✕   ⋮

> Automating tests for your codebase makes development more predictable and less risky.

Testing overview

Lines of production code

21%
Test code percentage

> Add tests for existing code every time you change it.

> For small systems (less than 1,000 lines of code), you should have at least some test code and one assertion (currently only checked for Java and C# systems).

> For medium systems (less than 10,000 lines of code), the total lines of test code should be at least 50% of the total lines of production code, and the assert density (percentage of lines of test code containing assertions) should be at least 1% (currently only checked for Java and C# systems).

> For large systems (more than 10,000 lines of code), the total lines of test code should be at least 50% of the total lines of production code, and the assert density should be at least 5% (currently only checked for Java and C# systems).

Write Clean Code ✓ ⋮

Guideline

Refactoring candidates

> Clean code is more maintainable.

> Proactively search and remove code smells.

> Remove useless comments, commented code blocks, and dead code. Refactor poorly handled exceptions, magic constants, and poorly names units or variables.
